

How Data Travels When I Search in Zomato

When I open Zomato on my smartphone and search for something like “**Pizza**”, the following process happens:

1. **Search request starts from my device:** I type “Pizza” in the search bar and press the **Search** button. My smartphone creates a digital request containing information such as the search keyword and other relevant app data.
2. **Request goes through a network:** If I am using Wi Fi, the request travels from my **smartphone to the Wi Fi router**. If I am using 4G or 5G, it travels through the **mobile network tower** instead.
3. **ISP sends the request to the Internet:** The Wi Fi router forwards the request to the **Internet Service Provider (ISP)**. The ISP connects my local network to the wider **Internet (WAN)** and routes the request toward Zomato’s online servers.
4. **Zomato server processes the search:** The request reaches Zomato’s server. The server checks its database for matching restaurants, pizza items, delivery availability, and other relevant information based on the request.
5. **Results travel back to my phone:** The server sends the search results back through the **Internet → ISP → Wi Fi router/mobile network → smartphone**. The Zomato app then displays the matching pizza restaurants and food items on my screen.

Simple-data-flow:

Smartphone → Wi Fi Router / Mobile Network → ISP → Internet → Zomato Server → Internet → ISP → Router/Mobile Network → Smartphone
