

Q-Given a scenario where a user tries to log into a network device but fails authentication, describe how RADIUS and TACACS+ would handle the logging and response differently.

Hint: Focus on how each protocol manages accounting and command authorization.

Aspect	RADIUS	TACACS+
Authentication failure	RADIUS server sends Access-Reject to the network device.	TACACS+ server sends a REJECT response to the network device.
Logging / Accounting	RADIUS can record authentication/accounting information, such as login attempts and session information.	TACACS+ provides detailed accounting of administrative sessions and activities.
Command authorization	Generally not designed for detailed per-command authorization on network devices.	Can authorize individual commands , so administrators can control exactly what commands a user may execute.
After failed login	Device denies access; an accounting record may be generated depending on configuration.	Device denies access, and TACACS+ can maintain detailed administrative accounting when a session exists.

Simple example

RADIUS:

User → Router → RADIUS Server

Wrong password

Access-Reject

Login denied

TACACS+:

User → Router → TACACS+ Server

Wrong password

REJECT

Login denied

If login succeeds → TACACS+ can authorize

individual commands + record administrative activity

RADIUS is commonly used for **network access**, while TACACS+ is particularly suited to **network-device administration**, where detailed command authorization and accounting are important.
