

Scenario: Ordering Food on Zomato

I open the **Zomato** app on my smartphone and select a restaurant to order dinner. My phone first connects wirelessly to the **Access Point (AP)** (or the Wi-Fi feature built into my home router). The access point receives the data from my phone and forwards it into the local network.

Next, the data reaches the **Switch**, which directs the network traffic to the correct destination within the local network. Unlike a hub, the switch sends the data only to the intended device, making communication faster and more efficient.

The data then arrives at the **Router**. The router acts as the gateway between my home network and the Internet. It assigns local IP addresses, determines the best path for the data, and forwards my order request to Zomato's servers over the Internet.

Once Zomato processes the order, the confirmation travels back through the Internet to my **Router**, then through the **Switch**, and finally to the **Access Point**, which wirelessly delivers the response to my smartphone. Within a few seconds, I see the message "**Your order has been placed successfully!**"
