

Motherboard — The large green circuit board that everything else plugs into. It connects all components and allows them to communicate with each other.

CPU (Central Processing Unit) — The brain of the computer. It executes all instructions and calculations that make programs run.

CPU Cooler — Sits directly on top of the CPU (fan + heatsink, or liquid cooler). Keeps the processor from overheating during heavy use.

RAM (Random Access Memory) — The sticks of memory plugged into slots on the motherboard. They temporarily hold data the CPU is actively working with — more RAM = better multitasking.

GPU (Graphics Card) — A large card slotted into the PCIe slot. It processes and renders all visuals, making it essential for gaming, video editing, and 3D work.

Chipset — A chip soldered onto the motherboard that manages data traffic between the CPU, RAM, storage, and other peripherals.

SSD / HDD (Storage Drive) — Permanently stores your operating system, games, and files. SSDs are fast and silent; HDDs are slower but offer more storage for the price.

Case Fans — Mounted on the front, rear, or top of the cabinet. They pull cool air in and push hot air out to maintain airflow.

PSU (Power Supply Unit) — Sits at the bottom (or top) of the case. Converts wall power (AC) into the lower DC voltages that all PC components need.
