

The IPL Streaming + Gaming PC

For a gaming PC built for streaming IPL matches while simultaneously running graphics-heavy games, I would choose **liquid cooling (AIO)**. Streaming and gaming at the same time is a dual workload — the CPU encodes the video stream while the GPU renders the game, pushing both components to sustained high temperatures for hours on end. Air cooling handles short bursts well but struggles during long sessions, and thermal throttling could cause frame drops mid-match or stream stutters at a crucial moment. Liquid cooling's 10–20°C temperature advantage ensures the GPU stays in its peak performance range throughout a full IPL innings. The quieter operation is also a bonus — with a mic live for commentary or voice chat, loud GPU fans in the background are a real problem that liquid cooling largely eliminates.
