

Here's the full troubleshooting flow

Step 1 — Toggle Bluetooth. The first thing to do is turn Bluetooth off on your phone, wait about 5 seconds, then turn it back on. This clears any frozen connection state. On iPhone: Settings → Bluetooth. On Android: quick-panel toggle or Settings → Connected devices.

Step 2 — Tap to pair. Tap the device name and watch for a "Connected" confirmation. If it spins or throws an error, the saved pairing record is likely corrupted.

Step 3 — Forget & re-pair. On iPhone, tap the ⓘ icon next to the device name → "Forget This Device." On Android, long-press the name → "Unpair." Then re-initiate pairing fresh.

Step 4 — Force pairing mode on the headphones. Most headphones enter pairing mode by holding the power button for 5–8 seconds until an LED flashes a repeating blue/red pattern (or you hear an audio cue). This makes them "undiscovered" and ready to pair as a new device.

Step 5 — Clear saved devices on the phone. Phones sometimes have trouble when too many devices are stored. Remove old, unused Bluetooth devices from your list to free up slots.

Step 6 — Factory reset the headphones. This wipes all paired devices stored on the headphones themselves. The combo varies — commonly it's holding power + volume down simultaneously for 10 seconds. Check the manufacturer's manual or their support page for the exact sequence.

Step 7 — Hardware / support. If nothing above works: check that the headphones have battery charge, try pairing with a completely different phone to isolate whether the fault is the headphones or your phone, then reach out to warranty/support if the issue is device-side.
