

IPv4	IPv6
Uses a 32-bit address.	Uses a 128-bit address.
Address is written in four decimal numbers separated by dots (for example: 192.168.1.1).	Address is written in eight groups of hexadecimal numbers separated by colons (for example: 2001:db8::1).
Has a limited number of IP addresses, so they can run out.	Provides a much larger number of IP addresses, so there is plenty of address space.
Often uses NAT (Network Address Translation) because of the shortage of addresses.	Usually does not need NAT because enough addresses are available for every device.
